# Local variable selection and parameter estimation for spatially varying coefficient models

Wesley Brooks

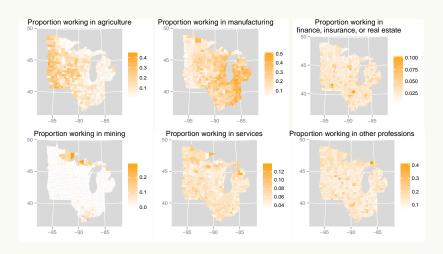

Department of Statistics
University of Wisconsin–Madison

January 17, 2014

#### Response variable

#### Covariates

#### Scientific questions

- ► Which of the economic-structure variables is associated with poverty rate?
- What are the sign and magnitude of that association?
- Is poverty rate associated with the same economic-structure variables across the entire region?
- ► How do the sign and magnitude of the associations vary across the region?

#### An overview

- Definitions
- Spatial regression
- Varying coefficient regression
  - Splines
  - Wavelets
- Model selection via regularization

#### **Definitions**

- ▶ Univariate spatial response process  $\{Y(s) : s \in \mathcal{D}\}$
- ▶ Multivariate spatial covariate process  $\{X(s) : s \in \mathcal{D}\}$
- ightharpoonup n = number of observations
- ▶ p = number of covariates
- ► Location (2-dimensional) s
- ► Spatial domain *D*

Spatial linear regression (Cressie, 1993)

A typical spatial linear regression model

$$Y(s) = X(s)'\beta + W(s) + \varepsilon(s)$$

- ightharpoonup W(s) is a spatial random effect that accounts for autocorrelation in the response variable
- ightharpoonup arepsilon(s) is iid random noise
- ▶ The coefficients  $\beta = (1, \beta_1, \dots, \beta_p)$  are constant
- Requires a priori global variable selection

Spatially varying coefficient model (Gelfand et al., 2003)

A more flexible model: coefficients in a spatial regression model can vary

$$Y(s) = X(s)'\beta(s) + \varepsilon(s)$$

- $\{\beta_0(s): s \in \mathcal{D}\}, \dots, \{\beta_p(s): s \in \mathcal{D}\}$  are stationary spatial processes
- Requires a priori global variable selection

Varying coefficients regression (VCR) (Hastie and Tibshirani, 1993)

$$Y(s) = X(s)'\beta(s) + \varepsilon(s)$$

- Assume an effect modifying variable s
- Coefficients are functions of s

Global selection in spline-based VCR models

Global variable selection can be done via regularization in a VCR model where the coefficient functions are modeled as splines

- ▶ The  $L_2$  norm of a function (e.g.  $\int \{f(t)\}^2 dt$ ) is zero if and only if the function is zero everywhere.
- Use regularization to penalize nonzero coefficient functions
  - SCAD penalty and B-splines (Wang et al., 2008a)
  - Non-negative garrote penalty and P-splines (Antoniadis et al., 2012b)

Wavelet methods for VCR models

- Wavelet methods: decompose coefficient function into local frequency components
- Selection of nonzero local frequency components with nonzero coefficients:
  - Bayesian variable selection (Shang, 2011)
  - Lasso (Zhang and Clayton, 2011)
- Sparsity in the local frequency components; not in the local covariates

Brundson et al. (1998), Fotheringham et al. (2002)

- ► Consider observations at sampling locations s<sub>1</sub>,...,s<sub>n</sub>
- $y(s_i) = y_i$  the univariate response at location  $s_i$
- ullet  $oldsymbol{x}(oldsymbol{s}_i) = oldsymbol{x}_i$  the p-vector of covariates at location  $oldsymbol{s}_i$
- ► Assume  $y_i = x_i'\beta_i + \varepsilon_i$  where  $\varepsilon_i \stackrel{iid}{\sim} \mathcal{N}\left(0, \sigma^2\right)$

Brundson et al. (1998), Fotheringham et al. (2002)

► The total log likelihood is

$$\ell\left(\boldsymbol{\beta}\right) = -\left(1/2\right) \left\{ n \log\left(2\pi\sigma^2\right) + \sigma^{-2} \sum_{i=1}^{n} \left(y_i - \boldsymbol{x}_i' \boldsymbol{\beta}_i\right)^2 \right\}$$

- ▶ With n observations and np + 1 parameters, the model is not identifiable.
- Idea: to estimate parameters by borrowing strength from nearby observations

Local regression (Loader, 1999)

Local regression uses a kernel function at each sampling location to weight observations based on their distance from the sampling location.

$$\begin{aligned} \mathcal{L}_i &= \prod_{i'=1}^n \left(\mathcal{L}_{i'}\right)^{w_{ii'}} \\ \ell_i &= \sum_{i'=1}^n w_{ii'} \left\{ \log \left(\sigma^2\right) + \sigma^{-2} \left(y_{i'} - \boldsymbol{x}'_{i'} \boldsymbol{\beta}_i\right)^2 \right\} \end{aligned}$$

Given the weights, a local model is fit at each sampling location using the local likelihood

Local likelihood (Loader, 1999)

Weights are calculated via a kernel, e.g. the bisquare kernel:

$$w_{ii'} = \begin{cases} \left\{ 1 - (\phi^{-1}\delta_{ii'})^2 \right\}^2 & \text{if } \delta_{ii'} < \phi, \\ 0 & \text{if } \delta_{ii'} \ge \phi \end{cases}$$
 (1)

#### where

- $ightharpoonup \phi$  is a bandwidth parameter
- ▶  $\delta_{ii'} = \delta(s_i, s_{i'}) = ||s_i s_{i'}||_2$  is the Euclidean distance between sampling locations  $s_i$  and  $s_{i'}$ .

Bandwidth estimation via the AIC<sub>c</sub> (Hurvich et al., 1998)

- Smaller bandwidth: less bias, more flexible coefficient surface
- Large bandwidth: less variance, less flexible coefficient surface
- Choose the bandwidth parameter to optimize the bias-variance tradeoff

Bandwidth estimation via the AIC<sub>c</sub> (Hurvich et al., 1998)

► The corrected AIC for bandwidth selection is:

$$\mathsf{AIC_c} = 2n\log\sigma + n\left\{\frac{n+\nu}{n-2-\nu}\right\}$$

- $\begin{aligned} & \ \hat{y} = Hy \\ & \ \nu = \operatorname{tr}(H) \\ & \ H_j = \left\{WX(X'WX)^{-1}X\right\}_i \end{aligned}$
- Where subscript j indicates the jth row of the matrix

# Geographically weighted Lasso

Geographically weighted Lasso (Wheeler, 2009)

Within a GWR model, using the Lasso for local variable selection is called the geographically weighted Lasso (GWL).

- The GWL requires estimating a Lasso tuning parameter for each local model
- ▶ Wheeler (2009) estimates the local Lasso tuning parameter at location  $s_i$  by minimizing a jacknife criterion:  $|y_i \hat{y}_i^{(-i)}|$
- The jacknife criterion can only be calculated where data are observed, making it impossible to use the GWL to impute missing data or to estimate the value of the coefficient surface at new locations
- ► Lasso not generally unbiased in variable selection (Fan and Li, 2001; Zou, 2006)

Geographically weighted adaptive elastic net (GWEN)

To overcome the shortcomings of the GWL, use a variable selection technique with potential for oracle properties and a tuning technique that can be applied anywhere on the domain.

- ► Local variable selection via the adaptive elastic net (AEN) (Zou and Zhang, 2009)
- ► Tuning parameters for local models selected by the BIC (Schwarz, 1978)

Geographically weighted adaptive elastic net (GWEN)

The adaptive elastic net:

$$S(\boldsymbol{\beta}_i) = -2\ell_i(\boldsymbol{\beta}_i) + \mathcal{J}_2(\boldsymbol{\beta}_i)$$

$$= \sum_{i'=1}^n w_{ii'} \left\{ \log \sigma_i^2 + (\sigma_i^2)^{-1} (y_{i'} - \boldsymbol{x}'_{i'} \boldsymbol{\beta}_i)^2 \right\}$$

$$+ \alpha_i \lambda_i \sum_{j=1}^p |\beta_{ij}| / |\gamma_{ij}|$$

$$+ (1 - \alpha_i) \lambda_i \sum_{j=1}^p (\beta_{ij} / \gamma_{ij})^2$$

Where

$$oldsymbol{\gamma}_i = \left(oldsymbol{X}'oldsymbol{W}_ioldsymbol{X}
ight)^{-1}oldsymbol{X}'oldsymbol{W}_ioldsymbol{Y}$$

Geographically weighted adaptive elastic net (GWAL)

► The adaptive Lasso penalty function is (Zou, 2006)

$$\mathcal{J}_1(\boldsymbol{\beta}_i) = \lambda_i \sum_{j=1}^p |\beta_{ij}| / |\gamma_{ij}|$$

 Under suitable conditions, the AL has an oracle property for selection in linear regression

Tuning parameter estimation

To estimate an AEN tuning parameter for each local model, use a local BIC that allows fitting a local model at any location within the spatial domain

$$\begin{split} \mathrm{BIC}_i &= -2\sum_{i'=1}^n \ell_{ii'} + \log\left(\sum_{i'=1}^n w_{ii'}\right) \mathrm{df}_i \\ &= \sum_{i'=1}^n w_{ii'} \left\{ \log\left(2\pi\right) + \log\left(\hat{\sigma}^2\right) + \hat{\sigma}^{-2} \left(y_{i'} - \boldsymbol{x}_{i'}' \hat{\boldsymbol{\beta}}_{i'}\right)^2 \right\} \\ &+ \log\left(\sum_{i'=1}^n w_{ii'}\right) \mathrm{df}_i \end{split}$$

#### Bandwidth parameter estimation

- Traditional GWR:
  - $-\hat{y} = Hy$
  - So traditional GWR is a linear smoother
  - $\nu = \operatorname{tr}(\boldsymbol{H})$  is the degrees of freedom for the model
- ► GWEN:
  - $\begin{aligned} & \ \hat{y} = \boldsymbol{H}^* \boldsymbol{y} \boldsymbol{T} \\ & \ \text{Where} \ T_i = \left\{ \boldsymbol{W}_i^{1/2} \boldsymbol{X} \left( \boldsymbol{X}' \boldsymbol{W}_i \boldsymbol{X} + (1 \alpha) \lambda I_p \right)^{-1} \frac{\lambda_i}{\gamma_i} \right\}_i \end{aligned}$
- GWEN is not a linear smoother
- Solution: use GWEN for selection then fit local model for the selected variables via traditional GWR

#### Locally linear coefficient estimation

- GWR, GWEN, GWAL: coefficients locally constant
  - as in Nadaraya-Watson kernel smoother
  - Leads to bias where there is a gradient at the boundary
  - Counter with locally linear coefficients
- ► Augment with covariate-by-location interactions:

$$Z_i = \begin{pmatrix} \tilde{X}_i & L_i \tilde{X}_i & M_i \tilde{X}_i \end{pmatrix}$$

#### Where

- ullet  $\tilde{X}_i$  is the matrix of covariates selected for the model at location  $s_i$
- $L_i = \text{diag}\{s_{i',x} s_{i,x}\}\ \text{for } i' = 1, \dots, n$
- $M_i = \text{diag}\{s_{i',y} s_{i,y}\}\ \text{for } i' = 1, \dots, n$

#### Simulating covariates

- ▶  $30 \times 30$  grid on  $[0,1] \times [0,1]$
- ▶ Five covariates  $\tilde{X}_1, \dots, \tilde{X}_5$
- Gaussian random fields:

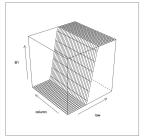

$$\begin{split} \tilde{X}_{j} \sim N\left(0, \mathbf{\Sigma}\right) \text{ for } j = 1, \dots, 5 \\ \left\{\Sigma\right\}_{i, i'} = \exp\{-\tau^{-1}\delta_{ii'}\} \text{ for } i, i' = 1, \dots, n \end{split}$$

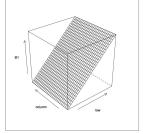

- Colinearity: ρ
  - none ( $\rho = 0$ )
  - moderate ( $\rho = 0.5$ )

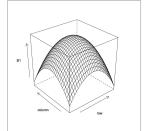

#### Simulating the response

- $Y(s) = X(s)'\beta(s) = \sum_{j=1}^{5} \beta_j(s)X_j(s) + \varepsilon(s)$
- ▶  $\beta_1(s)$ , the coefficient function for  $X_1$ , is nonzero in part of the domain.
- ▶ Coefficients for  $X_2, ..., X_5$  are zero everywhere
- $ightharpoonup \varepsilon(s) \sim iid N(0, \sigma^2)$ 
  - Low noise:  $\sigma = 0.5$
  - High noise:  $\sigma = 1$

Coefficient functions: step, gradient, and parabola

Simulation settings
Each setting simulated 100 times:

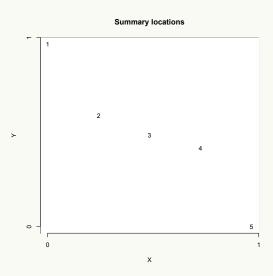

Setting	function	ρ	$\sigma^2$
1	step	0	0.25
2	step	0	1
3	step	0.5	0.25
4	step	0.5	1
5	gradient	0	0.25
6	gradient	0	1
7	gradient	0.5	0.25
8	gradient	0.5	1
9	parabola	0	0.25
10	parabola	0	1
11	parabola	0.5	0.25
12	parabola	0.5	1

#### Estimation methods

method	selection	locally linear
GWR	NA	
oracular GWR	oracle	X
GWEN	GWEN	
GWAL	GWAL	
<b>GWEN-LLE</b>	GWEN	Χ
<b>GWAL-LLE</b>	GWAL	X
	1	

# Simulation results

#### Summary locations

#### Simulation results

#### Selection performance

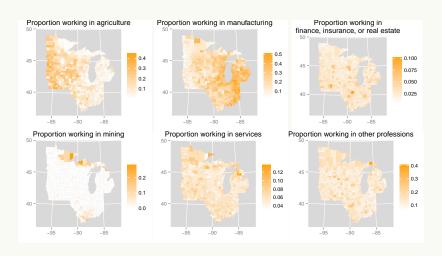

- GWEN selection (60 cases):
  - 21 with no false positives
  - 30 with no false negatives
  - 13 with neither
- GWAL selection (60 cases):
  - 27 with no false positives
  - 26 with no false negatives
  - 17 with neither
- Selection errors almost always below five percent
- Worst false positive rate: 8% at location three of the step function (GWEN selection)
- Worst false negative rate: 13% (same location, GWAL selection)
- No consistent difference between GWEN and GWAL

### Simulation results

### Estimation performance

- Cases where oracular GWR clearly had the best performance
  - Minimum MSE( $\hat{\beta}_1$ ): 38 of 60
  - Minimum  $var(\hat{\beta}_1)$ : 44 of 60
- Generally small differences between GWR, oracular GWR, GWEN-LLE, and GWAL-LLE
- Methods with locally constant coefficients had larger bias at the boundaries
- ▶ Fitting  $\hat{y}$ : MSE nearest  $\sigma^2$  split between GWAL-LLE, oracle, and GWR

### Revisiting the motivating example

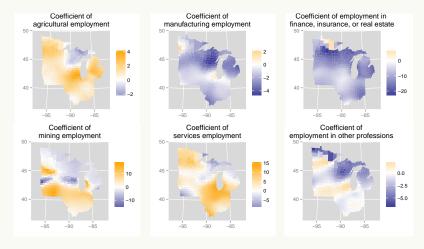

### Data description

- Response: logit-transformed poverty rate in the Upper Midwest states of the U.S.
  - Minnesota, Iowa, Wisconsin, Illinois, Indiana, Michigan
- Covariates: employment structure (raw proportion employed in:)
  - agriculture
  - finance, insurance, and real estate
  - manufacturing
  - mining
  - services
  - other professions
- Data source: U.S. Census Bureau's decennial census of 1970

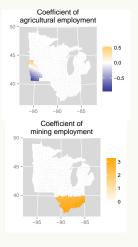

### Data description

- Data aggregated to the county level
  - counties are areal units
- county centroid treated as sampling location

#### Results from traditional GWR

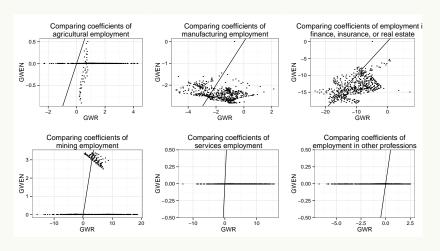

#### Results from GWEN

### Comparing the coefficients from GWR and the GWEN

#### Results from GWEN-LLE

- Relatively constant compared to GWR
- Not associated with poverty rate: Services, "other professions" sector
- Manufacturing: negative coefficient everywhere
- ► Finance, insurance, and real estate negative coefficient everywhere
  - Largest magnitude (min: -20, next-largest: -3)
  - GWR comparable to GWEN-LLE
- Manufacturing: negative coefficient everywhere
  - GWR: coefficient greater than zero near Chicago and in NW Minnesota
- Agriculture: nonzero in western lowa
  - North-south gradient to coefficient
  - ranges positive to negative
- Mining: nonzero in parts south
  - Associated with increased poverty rate
  - Comparable to GWR within far southern range

# Future work

### Future work

- Apply the GWEN to models for non-Gaussian response variable
- Investigate the asymptotic properties of the GWEN
- Incorporate spatial autocorrelation in the model
- PalEON project: modeling and mapping tree biomass in the upper midwest

# Thank you!
